

Phase transition of measure for branching process in random environment

Makoto Nakashima

Division of Mathematics, Graduate School of Science, Kyoto University

We consider the branching processes in random environment which are given as random variables in time-space. In this model, a phase transition occurs for growth rate of the total population according to environment. More precisely, the growth rate of the total population is the same as its the one of the mean of the total population or is slower than it. We look at the behavior for the population density for each phase.
